

8.1 Heaps

Heap concept

Some applications require fast access to and removal of the maximum item in a changing set of items. For example, a computer may execute jobs one at a time; upon finishing a job, the computer executes the pending job having maximum priority. Ex: Four pending jobs have priorities 22, 14, 98, and 50; the computer should execute 98, then 50, then 22, and finally 14. New jobs may arrive at any time.

Maintaining jobs in fully-sorted order requires more operations than necessary, since only the maximum item is needed. A **max-heap** is a complete binary tree that maintains the simple property that a node's key is greater than or equal to the node's children's keys. (Actually, a max-heap may be any tree, but is commonly a binary tree). Because $x \geq y$ and $y \geq z$ implies $x \geq z$, the property results in a node's key being greater than or equal to all the node's descendants' keys. Therefore, a *max-heap's root always has the maximum key in the entire tree*.

Figure 8.1.1: Max-heap property: A node's key is greater than or equal to the node's children's keys.

PARTICIPATION ACTIVITY

8.1.1: Max-heap property.

Consider this binary tree:

1) 33 violates the max-heap property due to being greater than 22.

- ☐ True
☐ False

2) 54 violates the max-heap property due to being greater than 44.

- ☐ True
☐ False

3) 60 violates the max-heap property due to being greater than 55.

- ☐ True
☐ False

4) A max-heap's root must have the maximum key.

- ☐ True
☐ False

Max-heap insert and remove operations

An **insert** into a max-heap starts by inserting the node in the tree's last level, and then swapping the node with its parent until no max-heap property violation occurs. Inserts fill a level (left-to-right) before adding another level, so the tree's height is always the minimum possible. The upward movement of a node in a max-heap is called **percolating**.

A **remove** from a max-heap is always a removal of the root, and is done by replacing the root with the last level's last node, and swapping that node with its greatest child until no max-heap property violation occurs. Because upon completion that node will occupy another node's location (which was swapped upwards), the tree height remains the minimum possible.

IASTATECOMS228Spring2021

Min-heap

A **min-heap** is similar to a max-heap, but a node's key is less than or equal to its children's keys.

Example 8.1.1: Online tech support waiting lines commonly use min heaps.

Many companies have online technical support that lets a customer chat with a support agent. If the number of customers seeking support is greater than the number of available agents, customers enter a virtual waiting line. Each customer has a priority that determines their place in line. The customer with the highest priority is served by the next available agent.

A min heap is commonly used to manage prioritized queues of customers awaiting support. Customers that entered the line earlier and/or have a more urgent issue get assigned a lower number, which corresponds to a higher priority. When an agent becomes available, the customer with the lowest number is removed from the heap and served by the agent.

PARTICIPATION ACTIVITY

8.1.4: Min heaps and customer support.

- 1) A customer with a higher priority has a lower numerical value in the min heap.
 - ☐ True
 - ☐ False
- 2) If 2,000 customers are waiting for technical support, removing a customer from the min heap requires about 2,000 operations.

8.2 Heaps using arrays

Heap storage

Heaps are typically stored using arrays. Given a tree representation of a heap, the heap's array form is produced by traversing the tree's levels from left to right and top to bottom. The root node is always the entry at index 0 in the array, the root's left child is the entry at index 1, the root's right child is the entry at index 2, and so on.

Parent and child indices

Because heaps are not implemented with node structures and parent/child pointers, traversing from a node to parent or child nodes requires referring to nodes by index. The table below shows parent and child index formulas for a heap.

Table 8.2.1: Parent and child indices for a heap.

Node index	Parent index	Child indices
0	N/A	1, 2
1	0	3, 4
2	0	5, 6
3	1	7, 8
4	1	9, 10
5	2	11, 12
...
i	$\lfloor (i - 1) / 2 \rfloor$	$2 * i + 1, 2 * i + 2$

8.3 Heap sort

Heapify operation

©zyBooks 05/10/21 12:45 728163

Neha Maddali

IASTATECOMS228Spring2021

Heapsort is a sorting algorithm that takes advantage of a max-heap's properties by repeatedly removing the max and building a sorted array in reverse order. An array of unsorted values must first be converted into a heap. The **heapify** operation is used to turn an array into a heap. Since leaf nodes already satisfy the max heap property, heapifying to build a max-heap is achieved by percolating down on every non-leaf node in reverse order.

PARTICIPATION ACTIVITY

8.3.1: Heapify operation.

Animation captions:

1. If the original array is represented in tree form, the tree is not a valid max-heap.
2. Leaf nodes always satisfy the max heap property, since no child nodes exist that can contain larger keys. Heapification will start on node 92.
3. 92 is greater than 24 and 42, so percolating 92 down ends immediately.
4. Percolating 55 down results in a swap with 98.
5. Percolating 77 down involves a swap with 98. The resulting array is a valid max-heap.

The heapify operation starts on the internal node with the largest index and continues down to, and including, the root node at index 0. Given a binary tree with N nodes, the largest internal node index is $\lfloor N/2 \rfloor - 1$.

Table 8.3.1: Max-heap largest internal node index.

Number of nodes in binary heap	Largest internal node index

☐ (10, 10, 10, 10)

Heapsort overview

Heapsort begins by heapifying the array into a max-heap and initializing an end index value to the size of the array minus 1. Heapsort repeatedly removes the maximum value, stores that value at the end index, and decrements the end index. The removal loop repeats until the end index is 0.

PARTICIPATION ACTIVITY

8.3.4: Heapsort.

©zyBooks 05/10/21 12:45 728163
Neha Maddali
IASTATECOMS228Spring2021

Animation captions:

1. The array is heapified first. Each internal node is percolated down, from highest node index to lowest.
2. The end index is initialized to 6, to refer to the last item. 94's "removal" starts by swapping with 68.
3. Removing from a heap means that the rightmost node on the lowest level disappears before the percolate down. End index is decremented after percolating.
4. 88 is swapped with 49, the last node disappears, and 49 is percolated down.
5. The process continues until end index is 0.
6. The array is sorted.

PARTICIPATION ACTIVITY

8.3.5: Heapsort.

Suppose the original array to be heapified is (11, 21, 12, 13, 19, 15).

8.4 Priority queue abstract data type (ADT)

Priority queue abstract data type

A **priority queue** is a queue where each item has a priority, and items with higher priority are closer to the front of the queue than items with lower priority. The priority queue **enqueue** operation inserts an item such that the item is closer to the front than all items of lower priority, and closer to the end than all items of equal or higher priority. The priority queue **dequeue** operation removes and returns the item at the front of the queue, which has the highest priority.

PARTICIPATION ACTIVITY

8.4.1: Priority queue enqueue and dequeue.

Animation content:

undefined

Animation captions:

1. Enqueueing a single item with priority 7 initializes the priority queue with 1 item.
2. If a lower numerical value indicates higher priority, enqueueing 11 adds the item to the end of the queue.
3. Since $5 < 7$, enqueueing 5 puts the item at the priority queue's front.
4. When enqueueing items of equal priority, the first-in-first-out rules apply. The 2nd item with priority 7 comes after the first.
5. Dequeue removes from the front of the queue, which is always the highest priority item.

PARTICIPATION ACTIVITY

8.4.2: Priority queue enqueue and dequeue.

Assume that lower numbers have higher priority and that a priority queue currently holds items: 54, 71, 86 (front is 54).

- 1) Where would an item with priority 60 reside after being enqueued?

☐ Before 54

☐ After 54

☐ After 86
- 2) Where would an additional item with priority 54 reside after being enqueued?

☐ Before the first 54

☐

After the first 54

☐ After 86

3) The dequeue operation would return which item?

☐ 54

☐ 71

☐ 86

Neha Maddali
IASTATECOMS228Spring2021

Common priority queue operations

In addition to enqueue and dequeue, a priority queue usually supports peeking and length querying. A **peek** operation returns the highest priority item, without removing the item from the front of the queue.

Table 8.4.1: Common priority queue ADT operations.

Operation	Description	Example starting with priority queue: 42, 61, 98 (front is 42)
Enqueue(PQueue, x)	Inserts x after all equal or higher priority items	Enqueue(PQueue, 87). PQueue: 42, 61, 87, 98
Dequeue(PQueue)	Returns and removes the item at the front of PQueue	Dequeue(PQueue) returns 42. PQueue: 61, 98
Peek(PQueue)	Returns but does not remove the item at the front of PQueue	Peek(PQueue) returns 42. PQueue: 42, 61, 98
IsEmpty(PQueue)	Returns true if PQueue has no items	IsEmpty(PQueue) returns false.
GetLength(PQueue)	Returns the number of items in PQueue	GetLength(PQueue) returns 3.

Neha Maddali
IASTATECOMS228Spring2021

Enqueueing items with priority

A priority queue can be implemented such that each item's priority can be determined from the item itself. Ex: A customer object may contain information about a customer, including the customer's name and a service priority number. In this case, the priority resides within the object.

A priority queue may also be implemented such that all priorities are specified during a call to **EnqueueWithPriority**: An enqueue operation that includes an argument for the enqueued item's priority.

8.5 Treaps

Treap basics

A BST built from inserts of N nodes having random-ordered keys stays well-balanced and thus has near-minimum height, meaning searches, inserts, and deletes are $O(\log N)$. Because insertion order may not be controllable, a data structure that somehow randomizes BST insertions is desirable. A **treap** uses a main key that maintains a binary search tree ordering property, and a secondary key generated randomly (often called "priority") during insertions that maintains a heap property. The combination usually keeps the tree balanced. The word "treap" is a mix of tree and heap. This section assumes the heap is a max-heap. Algorithms for basic treap operations include:

- A treap **search** is the same as a BST search using the main key, since the treap is a BST.
- A treap **insert** initially inserts a node as in a BST using the main key, then assigns a random priority to the node, and percolates the node up until the heap property is not violated. In a heap, a node is moved up via a swap with the node's parent. In a treap, a node is moved up via a *rotation at the parent*. Unlike a swap, a rotation maintains the BST property.
- A treap **delete** can be done by setting the node's priority such that the node should be a leaf ($-\infty$ for a max-heap), percolating the node down using rotations until the node is a leaf, and then

removing the node.

PARTICIPATION ACTIVITY

8.5.1: Treap insert: First insert as a BST, then randomly assign a priority and use rotations to percolate node up to maintain heap.

Animation captions:

1. The keys maintain a BST, the priorities a heap. Insert B as a BST...
2. Assign random priority (70). Rotate (which keep a BST) the node up until the priorities maintain a heap: 20 not $>$ 70: Rotate. 47 not $>$ 70: Rotate. 80 $>$ 70: Done.

PARTICIPATION

ACTIVITY

8.5.3: Treap insert.

When performing an insert, indicate each node's new location using the template tree's labels (n1...n7).

- 1) Where will a new node H first be inserted?

Check

Show answer

- 2) H is assigned a random priority of 20. To where does H percolate?

Check

Show answer

- 3) Where will a new node P first be inserted?

Check

Show answer

- 4) P is assigned a random priority of 65. To where does P percolate?

Check

Show answer

PARTICIPATION
ACTIVITY

8.5.4: Treap insert.

Node D was just inserted, and assigned a random priority of 47. Rotations are needed to not violate the heap property. Match the node value to the corresponding location in the tree

template on the right after the rotations are completed.

Treap delete

A treap delete could be done by first doing a BST delete (copying the successor to the node-to-delete, then deleting the original successor), followed by percolating the node down until the heap property is not violated. However, a simpler approach just sets the node-to-delete's priority to $-\infty$ (for a max-heap), percolates the node down until a leaf, and removes the node. Percolating the node down uses rotations, not swaps, to maintain the BST property. Also, the node is rotated in the direction of the lower-priority child, so that the node rotated up has a higher priority than that child, to keep the heap property.

PARTICIPATION ACTIVITY

8.5.5: Treap delete: Set priority such that node must become a leaf, then percolate down using rotations.

Animation captions:

1. Node F is to be deleted. First set F's priority to $-\infty$.
2. Rotate (to keep a BST) until the node becomes a leaf node. $29 > 13$: Rotate right.

3. Rotate until node becomes a leaf node. Rotate left (the only option).
4. Remove leaf node.

**PARTICIPATION
ACTIVITY**
8.5.6: Treap delete algorithm.

Each question starts from the original tree. Use this text notation for the tree: $(J(F(C, G), Q(M, T)))$. A - means the child does not exist.

1) What is the tree after removing G?

- ☐ $(J(F(C, -), Q(M, T)))$
☐ $(J(C(-, F), Q(M, T)))$

2) What is the tree after removing Q?

- ☐ $(J(F(C, G), M(-, T)))$
☐ $(J(F(C, G), T(M, -)))$

**PARTICIPATION
ACTIVITY**
8.5.7: Treaps.

1) A treap's nodes have random main keys.

- ☐ True
☐ False

2) A treap's nodes have random priorities.

- ☐ True
☐ False

3) Suppose a treap is built by inserting nodes with main keys in this order: A, B, C, D, E, F, G. The treap will have 7 levels,

with each level having one node with a right child.

- ☐ True
- ☐ False
